

With a virtual memory system:

- Can we meet all of the allocation requests?
- Are we limited to just RAM?

Simple Simulation of Page Tables with Disk Pages

| RAM: | P1 Page Table: | Disk Pages:         |  |
|------|----------------|---------------------|--|
| [0]: | [0]:           | ...                 | 1: Load Program  |
| [1]: | [1]:           | ./programCode (1/5) | 2: Run PC, pg1:<br>- malloc(4000)  |
| [2]: | [2]:           | ./programCode (2/5) |  |
| [3]: | [3]:           | ./programCode (3/5) | 3: Run PC, pg2:<br>- malloc(10000)<br>- Open<br>hiddenImage.png<br>- Read all of image |
|      | [4]:           | ./programCode (4/5) |  |
|      | [5]:           | ./programCode (5/5) |  |
|      | [6]:           |                     |  |
|      | [7]:           |                     |  |
|      | [8]:           |                     |  |
|      | [9]:           |                     |  |
|      | [10]:          | hiddenImage.png     | 4: Run PC, pg3:<br>- Access OG 4 KB<br>- Finish program                                |
|      | [11]:          | hiddenImage.png     |  |
|      | [12]:          | hiddenImage.png     |  |
|      | [13]:          | hiddenImage.png     |  |
|      | [14]:          |                     |  |
|      | [15]:          | ...                 |  |

Q1: What is the range of possible file sizes for `hiddenImage.png`?

Q2: What is the range of possible file sizes for `./programCode`?

Q3: What is the size of the heap immediately before the program finishes?

Memory Allocation

Up until now, we have arbitrarily placed memory with the process page table – however, all modern Operating Systems (OSes) organize the memory of a process in a predictable way:

06/memory-addr.c

5

int val;

6

printf("&val: %p\n", &val);

7

8

void \*ptr = malloc(0x1000);

9

printf("&ptr: %p\n", &ptr);

10

printf(" ptr: %p\n", ptr);

11

12

void \*ptr2 = malloc(0x1000);

13

printf("&ptr2: %p\n", &ptr2);

14

printf(" ptr2: %p\n", ptr2);

15

16

int arr[4096];

17

printf("&arr: %p\n", &arr);

18

19

return 0;

Page Table:

|      |
|------|
|      |
|      |
|      |
|      |
|      |
|      |
| .... |
|      |
|      |
|      |
|      |
|      |
|      |
|      |
|      |

As a programmer, we talk about these different regions of memory as different “types” of memory:

Q: What if we access memory beyond the end of our heap? (Or any other region not allocated in our page table?)

Memory Address Components:

|          |  |  |
|----------|--|--|
| Address: |  |  |
|----------|--|--|

## Efficient Use of Heap Memory

During the lifetime of a single process, we will allocate and free memory many times. Consider a simple program:

| 06/heap.c |                        |                            |
|-----------|------------------------|----------------------------|
| 5         | int *a = malloc(4096); | Heap v1:                   |
| 6         | printf("a = %p\n", a); | (Without reuse after free) |
| 7         | free(a);               |                            |
| 8         |                        |                            |
| 9         | int *b = malloc(4096); | Heap v2:                   |
| 10        | printf("b = %p\n", b); | (With reuse after free)    |
| 11        |                        |                            |
| 12        | int *c = malloc(4096); |                            |
| 13        | printf("c = %p\n", c); |                            |
| 14        |                        |                            |
| 15        | int *d = malloc(4096); |                            |
| 16        | printf("d = %p\n", d); |                            |
| 17        |                        |                            |
| 18        | free(b);               |                            |
| 19        | free(c);               |                            |
| 20        |                        |                            |
| 21        | int *e = malloc(5000); |                            |
| 22        | printf("e = %p\n", e); |                            |
| 23        |                        |                            |
| 24        | int *g = malloc(10);   |                            |
| 25        | printf("g = %p\n", g); |                            |
| 26        |                        |                            |
| 27        | int *g = malloc(10);   |                            |
| 28        | printf("g = %p\n", g); |                            |

**Q2:** How much memory is used if we **do not** reuse memory?

**Q3:** How much memory is used with **optimal** reuse of memory?

- What happens to our memory over time?
- When we have “holes” in our heap, how do we decide what hole to use?

## Data Structures for Heap Management

When we manage heap memory, we need to use memory to help us store memory:

- Overhead:
- Allocated Memory:

## Metadata-based Approach to Memory Storage

| 06/heap.c |                        |                            |
|-----------|------------------------|----------------------------|
| 5         | int *a = malloc(4096); | Heap w/ Data Structures:   |
| 6         | printf("a = %p\n", a); | (Without reuse after free) |
| 7         | free(a);               |                            |
| 8         |                        |                            |
| 9         | int *b = malloc(4096); |                            |
| 10        | printf("b = %p\n", b); |                            |
| 11        |                        |                            |
| 12        | int *c = malloc(4096); |                            |
| 13        | printf("c = %p\n", c); |                            |
| 14        |                        |                            |
| 15        | int *d = malloc(4096); |                            |
| 16        | printf("d = %p\n", d); |                            |
| 17        |                        |                            |
| 18        | free(b);               |                            |
| 19        | free(c);               |                            |
| 20        |                        |                            |
| 21        | int *e = malloc(5000); |                            |
| 22        | printf("e = %p\n", e); |                            |
| 23        |                        |                            |
| 24        | int *g = malloc(10);   |                            |
| 25        | printf("g = %p\n", g); |                            |
| 26        |                        |                            |
| 27        | int *g = malloc(10);   |                            |
| 28        | printf("g = %p\n", g); |                            |
